Solar System Cycle System

Overview

How does the solar cycle work?

The solar cycle is driven by the Sun's magnetic field. The Sun's magnetic field is generated by the movement of charged particles within the Sun's interior. As the Sun rotates, this magnetic field becomes twisted and tangled, leading to the formation of sunspots and other solar phenomena.

What is a solar cycle?

solar cycle, period of about 11 years in which fluctuations in the number and size of sunspots and solar prominences are repeated. Sunspot groups have a magnetic field with a north and a south pole, and, in each 11-year rise and fall, the same polarity leads in a given hemisphere while the opposite polarity leads in the other.

What is the connection between solar cycles?

Examining the connection between solar Solar Cycles are the periodic changes in solar activity that occur roughly every 11 years. This activity is often measured by the number of Sunspots on the Sun's surface. These sunspots appear darker because they are cooler areas caused by the Sun's magnetic field.

What happens when the solar cycle is at a minimum?

When the solar cycle is at a minimum, active regions are small and rare and few solar flares are detected. These increase in number as the Sun approaches the maximum part of its cycle. Sometimes, the Sun throws off huge amounts of matter. These events are called coronal mass ejections, or CMEs.
